CYCLONE Multi-cloud Infrastructure for Data Intensive Applications

CYCLONE Architecture for Multi-cloud Applications

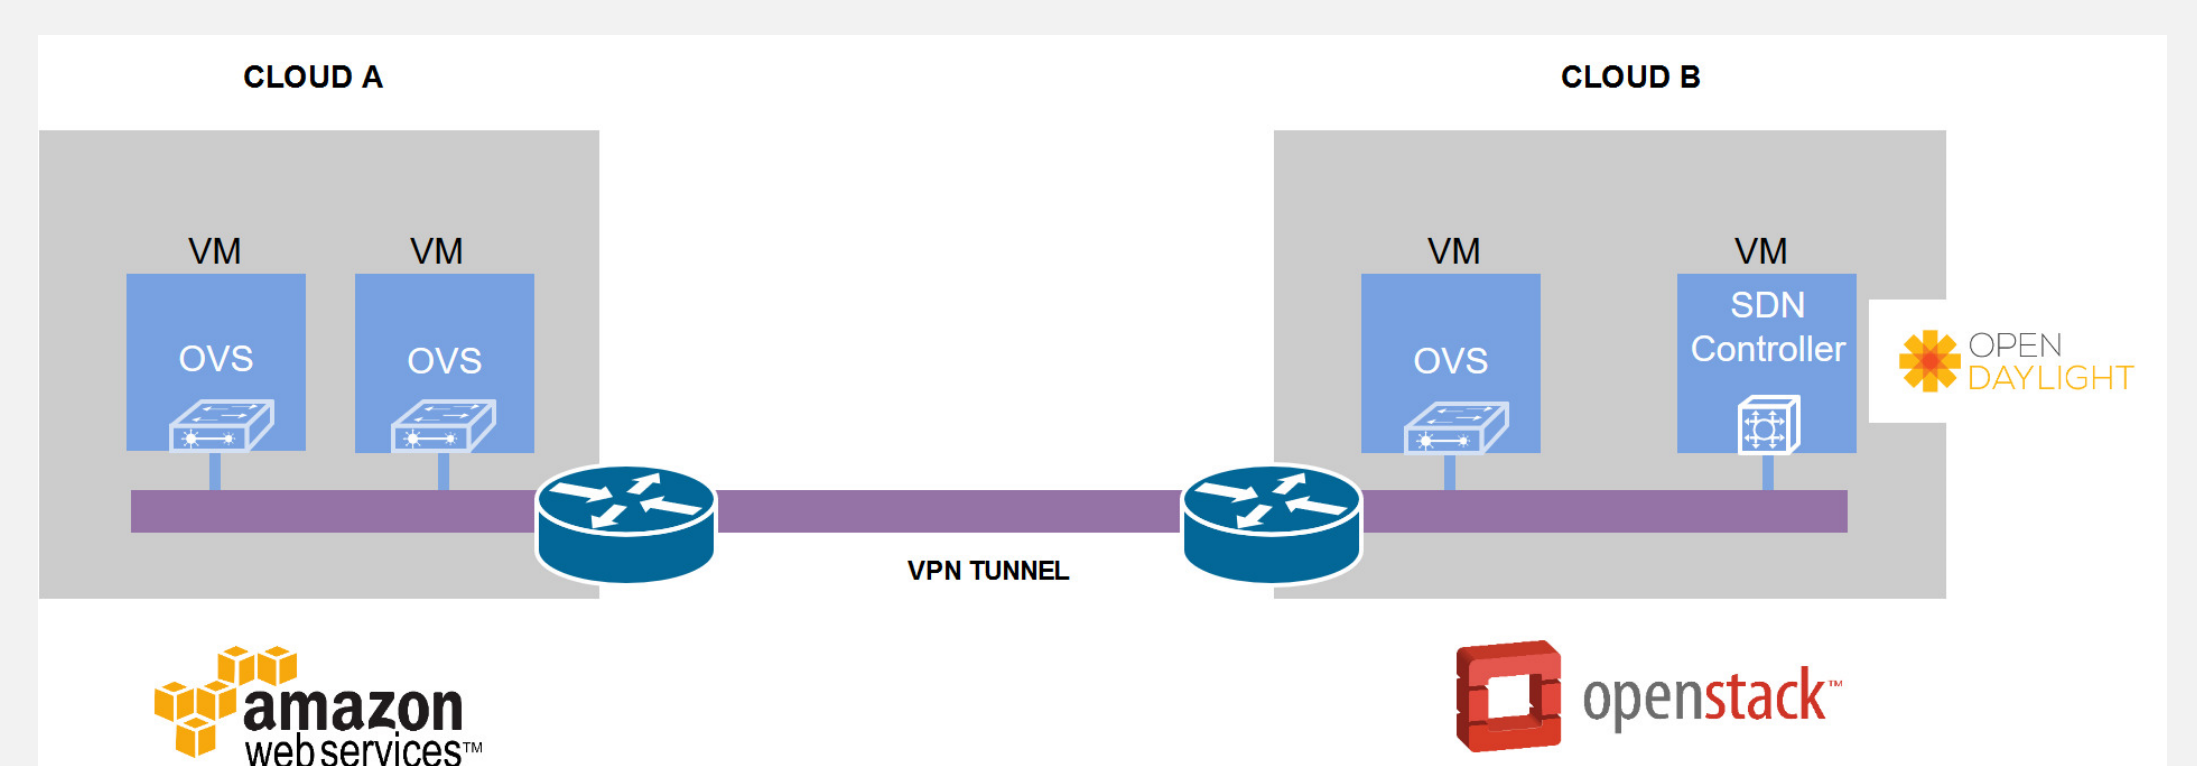

The CYCLONE Intercloud Architecture Framework addresses challenges related to heterogeneous multi-cloud applications

- Multilayer cloud resource integration, access control, management, and logging for multi-cloud applications
- On-demand multi-provider cloud service and infrastructure provisioning and life cycle management (composition, (re-)deployment, management, and monitoring)
- **Intra- and inter-cloud network provisioning between clouds, delivered as inter-cloud/multi-domain Virtual Private Network (VPN)**
- Access control, security credentials, and security context management covering the whole application life cycle
- Federated access to distributed multi-cloud resources, integrating application-based and cloud-based security services
- Data protection, including protection of data transfer between clouds as well as data storage in-rest.
- **CYCLONE approach:**
 - ✓ **Network Services** are built as overlay networks, created as a part of cloud application and working transparently on top of the underlying physical infrastructure.

CYCLONE Networking Services Using CNSMO

- CNSMO (Cyclone Network Services Manager and Orchestrator) is the software component responsible of deploying, configuring and running the networking services in cloud applications [1]
- CNSMO is based on the Software Defined Network paradigm, implementing an overlay network that will exploit the underlying connectivity given by ISPs
- Design is based on the virtual network bridge connecting the physical interface to a virtual switch, which is subscribed to an SDN controller that resides in one of the VMs on the same signalling VPN.
- SDN controller manages and monitors the network traffic across VMs instantiated in distributed clouds.
